abstract: The filter iterator adaptor creates a view of an iterator range in which some elements of the range are skipped. A predicate function object controls which elements are skipped. When the predicate is applied to an element, if it returns true then the element is retained and if it returns false then the element is skipped over. When skipping over elements, it is necessary for the filter adaptor to know when to stop so as to avoid going past the end of the underlying range. A filter iterator is therefore constructed with pair of iterators indicating the range of elements in the unfiltered sequence to be traversed.

```
filter_iterator synopsis

filter_iterator requirements

filter_iterator models

filter_iterator operations

Example
```

### filter\_iterator synopsis

```
template <class Predicate, class Iterator>
class filter_iterator
{
   public:
     typedef iterator_traits<Iterator>::value_type value_type;
     typedef iterator_traits<Iterator>::reference reference;
     typedef iterator_traits<Iterator>::pointer pointer;
     typedef iterator_traits<Iterator>::difference_type difference_type;
     typedef /* see below */ iterator_category;

filter_iterator();
   filter_iterator(Predicate f, Iterator x, Iterator end = Iterator());
   filter_iterator(Iterator x, Iterator end = Iterator());
   template<class OtherIterator>
```

filter\_iterator<P1, X> is interoperable with filter\_iterator<P2, Y> if and only if X is interoperable with Y.

# filter\_iterator operations

In addition to those operations required by the concepts that filter\_iterator models, filter\_iterator provides the following operations.

```
filter_iterator();
```

Requires: Predicate and Iterator must be Default Constructible.

Effects: Constructs a filter\_iterator whose "m\_pred", m\_iter, and m\_end members are a default constructed.

```
filter_iterator(Predicate f, Iterator x, Iterator end = Iterator());
```

Effects: Constructs a filter\_iterator where m\_iter is either the first position in the range [x,end) such that f(\*m\_iter) == true or else"m\_iter == end". The member m\_pred is constructed from f and m\_end from end.

```
filter_iterator(Iterator x, Iterator end = Iterator());
```

**Requires:** Predicate must be Default Constructible and Predicate is a class type (not a function pointer).

Effects: Constructs a filter\_iterator where m\_iter is either the first position in the range [x,end) such that m\_pred(\*m\_iter) == true or else"m\_iter == end". The member m\_pred is default constructed.

```
template <class OtherIterator>
filter_iterator(
    filter_iterator<Predicate, OtherIterator> const& t
    , typename enable_if_convertible<OtherIterator, Itera-
tor>::type* = 0 // exposition
    );''
```

Requires: OtherIterator is implicitly convertible to Iterator.

Effects: Constructs a filter iterator whose members are copied from t.

```
Predicate predicate() const;
```

```
Returns: m_pred

Iterator end() const;

Returns: m_end

Iterator const& base() const;

Returns: m_iterator

reference operator*() const;

Returns: *m_iter

filter_iterator& operator++();
```

Effects: Increments m\_iter and then continues to increment m\_iter until either m\_iter == m\_end or m\_pred(\*m\_iter) == true.

```
Returns: *this

template <class Predicate, class Iterator>
filter_iterator<Predicate,Iterator>
make_filter_iterator(Predicate f, Iterator x, Iterator end = Iterator());

Returns: filter_iterator<Predicate,Iterator>(f, x, end)

template <class Predicate, class Iterator>
filter_iterator<Predicate,Iterator>
make_filter_iterator(Iterator x, Iterator end = Iterator());

Returns: filter_iterator<Predicate,Iterator>(x, end)
```

# Example

This example uses filter\_iterator and then make\_filter\_iterator to output only the positive integers from an array of integers. Then make\_filter\_iterator is is used to output the integers greater than -2.

```
struct is_positive_number {
 bool operator()(int x) { return 0 < x; }</pre>
};
int main()
 int numbers_[] = { 0, -1, 4, -3, 5, 8, -2 };
 const int N = sizeof(numbers_)/sizeof(int);
 typedef int* base_iterator;
 base_iterator numbers(numbers_);
 // Example using filter_iterator
 typedef boost::filter_iterator<is_positive_number, base_iterator>
    FilterIter;
 is_positive_number predicate;
 FilterIter filter_iter_first(predicate, numbers, numbers + N);
 FilterIter filter_iter_last(predicate, numbers + N, numbers + N);
 std::copy(filter_iter_first, fil-
ter_iter_last, std::ostream_iterator<int>(std::cout, " "));
 std::cout << std::endl;</pre>
 // Example using make_filter_iterator()
 std::copy(boost::make_filter_iterator<is_positive_number>(numbers, num-
bers + N),
            boost::make_filter_iterator<is_positive_number>(numbers + N, num-
bers + N),
            std::ostream_iterator<int>(std::cout, " "));
 std::cout << std::endl;</pre>
 // Another example using make_filter_iterator()
```

```
std::copy(
    boost::make_filter_iterator(
        std::bind2nd(std::greater<int>(), -2)
        , numbers, numbers + N)

, boost::make_filter_iterator(
        std::bind2nd(std::greater<int>(), -2)
        , numbers + N, numbers + N)

, std::ostream_iterator<int>(std::cout, " ")
);

std::cout << std::endl;

return boost::exit_success;
}

The output is:

4 5 8
4 5 8
0 -1 4 5 8</pre>
```

The source code for this example can be found here.
